The carbon atom content of various hydrocarbon-containing moieties is indicated by a prefix designating the minimum and maximum number of carbon atoms in the moiety, i.e., the prefix C_{i-j} indicates a moiety of the integer "i" to the integer "j" carbon atoms, inclusive. Thus, for example, C₁₋₇alkyl refers to alkyl of one
30 to seven carbon atoms, inclusive.

Specific and preferred values listed below for radicals, substituents, and ranges are for illustration only; they do not exclude other defined values or other values within defined ranges for the radicals and substituents.

Schemes A-H describe the preparation of compounds of the present invention. All of the starting materials are prepared by procedures described in these schemes or

by procedures that would be well known to one of ordinary skill in organic chemistry. The variables used in the Schemes are as defined below or as in the claims.

Scheme A illustrates the preparation of tetrahydroisoquinolines, A-11. The known diol **A-1** (R_2 is hydrogen)(*J. Org. Chem.*, **1998**, 63, 4116-4119) is converted to the bis-mesylate **A-2** upon treatment with methanesulfonyl chloride in the presence of an appropriate base such as triethylamine. Treatment of **A-2** with benzylamine in an appropriate solvent such as methylene chloride then provides the ring-closed product, N-benzyl-6-nitrotetrahydroisoquinoline **A-3**. Simultaneous reduction of the nitro group and removal of the N-benzyl moiety by hydrogenation in the presence of an appropriate catalyst such as palladium-on-carbon in solvents such as methanol, ethanol, tetrahydrofuran or mixtures thereof and subsequent treatment with two equivalents of benzyl chloroformate and an appropriate base such as sodium bicarbonate provides the bis Cbz-protected 6-aminotetrahydroisoquinoline **A-4**. Structure **A-4** can then be converted to **A-11** through **A-5** and **A-6** by methods outlined in Scheme E. Alternatively, the aminomethyl oxazolidinone intermediate **A-6** can be protected as its Boc derivative **A-7** using di-t-butyl dicarbonate and sodium bicarbonate. Then, the Cbz protecting group of **A-7** can be removed via hydrogenation in the presence of an appropriate catalyst such as Pearlman's catalyst in a solvent such as methanol, ethanol, ethyl acetate, tetrahydrofuran or mixtures thereof to give the deprotected tetrahydroisoquinoline **A-8** which can be acylated by reactions well known to those skilled in the art to give the intermediates **A-9**. Treatment of **A-9** with HCl in a solvent such as methanol or dioxane or mixtures thereof provides the aminomethyl oxazolidinones **A-10** as their hydrochloride salts which can then be converted to the acetamide analogs **A-11** ($W = O$) upon treatment with acetic anhydride in the presence of a base such as pyridine or to the thioacetamide analogs **A-11** ($W = S$) upon treatment with ethyl dithioacetate in the presence of a base such as triethylamine.

Scheme B illustrates the preparation of the 2-acyl-1,2,3,4-tetrahydro-7-isoquinoline analogs **B-5**. The known 4-nitrohomophthalic acid (R_2 is hydrogen)(*J. Amer. Chem. Soc.*, **1969**, 91, 2467) can be reduced to the diol **B-2** according to the method described for the preparation of diol **A-1** in Scheme A (*J. Org. Chem.*, **1998**, 63, 4116-4119). Diol **B-2** can then be converted to the bis Cbz-protected 7-aminotetrahydroisoquinoline **B-3** using steps similar to those described in Scheme A for the conversion of **A-1** to **A-4**. Deprotonation of **B-3** with a base such as lithium t-

butoxide in a suitable solvent such as tetrahydrofuran, dimethylformamide or mixtures thereof in the presence of t-butyl (2S)-3-chloro-2-hydroxypropylcarbamate at a suitable temperature, typically in a range from 0°C to ambient temperature, then provides the Boc-protected aminomethyloxazolidinone **B-4**. The remaining steps which lead to the desired compounds **B-5** are similar to those described in Scheme A for the conversion of **A-7** to **A-11**.

Scheme C illustrates the preparation of the isochroman-6-yl and isothiochroman-6-yl oxazolidinone analogs. The nitro group of the known isochroman **C-1** (R_2 is hydrogen)(*J. Org. Chem.*, **1998**, 63, 4116-4119) is reduced by hydrogenation in the presence of an appropriate catalyst such as platinum oxide in a solvent such as methanol, ethanol, tetrahydrofuran or mixtures thereof, and the resulting amine can be converted to its Cbz derivative **C-2** upon treatment with benzyl chloroformate as described previously. For the corresponding isothiochroman, the bismesylate **C-3** can be treated with potassium thioacetate in an appropriate solvent such as dimethylformamide to afford the benzyl thioacetate **C-4** which is then S-deacetylated in the presence of ammonia in methanol with concomitant ring closure to give the isothiochroman **C-5**. In this case, the nitro group is reduced with stannous chloride in refluxing ethanol to afford the amine which is then converted to its Cbz derivative **C-6**. The carbamates **C-7** ($X = O, S$) can be converted to the desired analogs **C-8** using methods similar to those described in Scheme A. Alternatively, they can be deprotonated with a base such as lithium t-butoxide in a suitable solvent such as tetrahydrofuran, hexane, dimethylformamide or mixtures thereof in the presence of (1S)-2-acetylamino-1-(chloromethyl)ethyl acetate (*Tel. Lett.* **1996**, 37 (44) pp 7937-7940) at a suitable temperature, typically in a range from 0°C to ambient temperature, to provide the desired acetylaminomethyl oxazolidinones **C-8** ($X = O, S$; $Y = O$). Where X is S, the sulfur group can be oxidized with an appropriate oxidizing agent such as sodium periodate in an appropriate solvent such as a mixture of methanol and water or osmium tetroxide and N-methylmorpholine N-oxide in an appropriate solvent such as mixtures of acetone and water to give the corresponding sulfoxide and sulfone. In addition, where X is O, S, or SO_2 , treatment with Lawesson's reagent in refluxing tetrahydrofuran, dioxane or toluene gives the corresponding thioacetamides ($Y = S$).

Scheme D illustrates the preparation of the isochroman-7-yl and isothiochroman-7-yl oxazolidinone analogs. Diol **D-1** can be converted to the

isochroman **D-2** using a modified Mitsunobu reaction according to the method described for the preparation of isochroman **C-1** in Scheme C (*J. Org. Chem.*, **1998**, 63, 4116-4119). Using steps outlined previously in Scheme C, the nitro group of **D-2** is then reduced and the amine protected as its Cbz derivative to give **D-3**. Likewise, the nitro group of diol **D-1** can be reduced and the amine protected as its Cbz derivative to give diol **D-4**. Treatment of this diol with 2-3 equivalents of methanesulfonyl chloride in the presence of a base such as triethylamine provides the bismesylate **D-5** which, when treated with excess sodium sulfide in dimethylsulfoxide at a suitable temperature, typically in a range from 20 - 60°C, affords the isothiochroman **D-6**. The Cbz-protected 7-aminoisochroman and isothiochroman **D-7** (X = O, or S) are then converted to the desired analogs **D-8** using methods similar to those described in Scheme C.

Scheme E illustrates the preparation of the benzazepine compounds of the present invention. As shown in Scheme E, the known **E-1** (*J. Heterocyclic Chem.*, 1971, pp779-783) is treated with benzyl chloroformate (2 equivalents) in acetone and water with sodium bicarbonate to give **E-2**. The protected benzazepine thus prepared can be converted to the final oxazolidinone analogs as outlined in Scheme E. The carbamate derivatives **E-2** can be deprotonated with a lithium base such as *n*-butyllithium, lithium diisopropylamide (LDA), or lithium bis(trimethylsilyl)amide (LHMDS) in a suitable solvent such as THF, N,N-dimethylformamide (DMF), or mixtures thereof, at a suitable temperature, typically in a range from -78°C to -40°C to give a lithiated intermediate which is directly treated with R(-)-glycidyl butyrate. Warming to room temperature then affords (hydroxymethyl)oxazolidinones **E-3**. In cases where racemic starting materials are used, **E-3** is obtained as a mixture of two enantiomers. In the event that enantiomerically pure intermediates are employed, **E-3** is obtained as one enantiomer.

As shown in Scheme E, the hydroxymethyl derivatives can be converted to the corresponding **E-4** as mesylate (R' = Me) or nosylate (R' = 3-NO₂Ph) by treatment with methanesulfonyl chloride in the presence of triethylamine or pyridine, or methanitrophenylsulfonyl chloride in the presence of pyridine respectively. The resulting sulfonate can be treated with an alkali metal azide, such as potassium or sodium azide in an aprotic solvent such as DMF, or N-methylpyrrolidinone (NMP) with an optional catalyst such as 18-crown-6 at a temperature in the range of 50-90°C to afford azides.

The azides can be reduced to the corresponding amine **E-5** by hydrogenation in the presence of a palladium, platinum or nickel catalyst, in an appropriate solvent such as THF, ethyl acetate, or methanol. Alternatively, azides can be reduced to amines by treatment with triphenylphosphine or other trivalent phosphorous compounds in a solvent such as THF, followed by addition of water and heating to temperatures up to 65°C. A more direct route to the amines **E-5** is to reflux the sulfonates in isopropanol (or methanol)/THF/ammonium hydroxide under a dry ice/acetone condenser or in a pressure vessel. The amines **E-5** thus obtained can be acylated by reactions well known to those skilled in the art to give (acylaminomethyl)oxazolidinones of structural formula **E-8**. Furthermore, treatment of **E-8** (W = O) with Lawesson's reagent in refluxing toluene or THF will afford the corresponding thioamides (W = S). The Cbz-group of the (acylaminomethyl)oxazolidinones **E-6** can be removed via hydrogenation in the presence of an appropriate catalyst such as palladium on carbon in solvents such as THF, methanol, ethyl acetate, dichloromethane or mixtures thereof to afford deprotected intermediates of general structure **E-7** ($R^3 = H$). Alternatively, solvolysis of Cbz-derivatives **E-6** in 40% HBr/acetic acid followed by removal of solvent provides deprotected intermediates as hydrobromide salts. The deprotected materials can be acylated by reactions well known to those skilled in the art to give oxazolidinones **E-8** wherein R^3 is acyl. It can also be seen that other acyl derivatives, such as carbamates, can be prepared under similar conditions. In addition, the deprotected materials can be alkylated by reactions well known to those skilled in the art to give oxazolidinones of structural formula **E-8** wherein $R^3 = \text{alkyl}$.

As shown in Scheme F, the commercially available compound **F-1** is treated with hydroxyl amine and sodium acetate in ethanol and water followed by treatment with polyphosphoric acid to give the ring expanded structure **F-2**. Protection of the aryl amine of **F-2** with 2,5-hexanedione in toluene with an appropriate acid catalyst such as p-toluenesulfonic acid gives **F-3**. The amide is then reduced to the amine with lithium aluminum hydride in THF to give **F-4**. The protecting group is removed with hydroxyl amine and triethyl amine in ethanol and water to give the diamine **F-5** which is converted to **F-6** with benzyl chloroformate (2 equivalents) in acetone and water with sodium bicarbonate. The remaining steps which lead to the desired oxazolidinone analogs of type **F-7** are similar to these described in Scheme E.

As shown in Scheme G, beginning with the commercially available compound **G-1**, ring expansion with hydrazoic acid in chloroform or dichloromethane and

sulfuric acid gives the lactam **G-2**. Nitration of **G-2** with nitric acid in sulfuric acid gives **G-3**. Structure **G-3** is then reacted with a suitable borane such as borane in THF or borane-methyl sulfide complex in THF to give **G-4**. The nitro group can then be reduced by catalytic hydrogenation in the presence of a suitable catalyst such as

5 palladium on carbon in a suitable solvent such as methanol, ethanol, ethyl acetate, THF or combinations thereof provides amino intermediates. Alternatively, one can reduce the nitro group with palladium on carbon and hydrazine in methanol or ethanol. Treatment of the amino intermediates with benzyl chloroformate (2 equivalents) in THF with an appropriate base, such as sodium carbonate, potassium

10 carbonate or triethyl amine provides the bis-Cbz protected **G-5**. The remaining steps which lead to **G-5** to the desired oxazolidinone analogs of type **G-6** are similar to these described in Scheme E.

As shown in Scheme H, nitration of the known compound **H-1** can be accomplished using nitric acid in concentrated sulfuric acid (Himmelsbach DE

15 4429079) to afford **H-2**. The resulting diacid is reduced to the corresponding diol **H-3** using borane in THF or other appropriate reducing agents. Treatment of the diol with methanesulfonyl chloride, as described in Scheme D, affords the bismesylate **H-4**. Using steps outlined previously in Scheme C, the nitro group of **H-4** is then reduced and the amine protected as its Cbz derivative to give **H-5**. Similarly, the nitro group of

20 **H-4** can be reduced using tin II chloride in ethanol at 70 °C followed by Cbz protection of the free amine as described. Cyclization to the benzothiepin ring system is accomplished using sodium sulfide in dimethylsulfoxide as described in Scheme D to give **H-6**. The Cbz-protected benzothiepin **H-6** is then converted to the desired analog **H-7** using methods similar to those described in Scheme C.

25 Scheme I illustrates the preparation of the sulfoxide and sulfone analogs of **I-1**. Treatment of sulfide **I-1** with sodium metaperiodate in methanol and water affords the sulfoxide **I-2**. Likewise, oxidation to the sulfone **I-3** is accomplished using osmium tetroxide and N-methylmorpholine N-oxide. Similarly, oxidation can be accomplished using Oxone as the oxidant.

30 As shown in Scheme J, the Cbz-protected benzothiepin, **J-1** is converted to the Boc-protected aminomethyloxazolidinone **J-2** using conditions described in Scheme B. Removal of the Boc-protecting group and reaction of the resulting free amine with ethyl dithioacetate affords compound **J-3** using conditions described in Scheme A for the conversion of **A-9** to **A-11**. Using conditions described in Scheme I, **J-2** is first

oxidized to the sulfoxide and then converted to the thioacetamide, **J-5**, using conditions described in Scheme A. Similarly, **J-2** can be oxidized to the sulfone using conditions described in Scheme I and then converted to the thioacetamide using the conditions described in Scheme A to give **J-4**.

- 5 As outlined in Scheme K, the carbamate derivatives **K-1** ($R = C_{1-6}$ alkyl or benzyl) can be deprotonated with a lithium base such as n-butyllithium in a suitable solvent such as THF at a suitable temperature, typically in a range from -78°C to -40°C , to give a lithiated intermediate which is directly treated with R(-)-glycidyl butyrate. Warming to room temperature then affords the (5R)-hydroxymethyl
- 10 oxazolidinones **K-2**. In cases where racemic starting materials are used, **K-2** is obtained as a mixture of two enantiomers. The heteroaryl ethers **K-4** ($A = O$) can be obtained directly from the alcohols **K-2** under Mitsunobu conditions by treatment with het-OH (het is a heteroaryl ring defined previously) in the presence, for example, of free or polymer-bound triphenylphosphine and diethyl (or diisopropyl)
- 15 azodicarboxylate. Additionally, the alcohols **K-2** can be deprotonated with a base such as sodium hydride in a solvent such as DMF. Treatment with het-Lg, wherein Lg is an appropriate leaving group such as Br or Cl, then affords the heteroaryl ethers **K-4** ($A = O$).

- Alternatively, the alcohols **K-2** can be converted to their alkyl halides,
- 20 mesylates or tosylates **K-3** ($Lg = \text{Hal}, \text{OMs}, \text{OTs}$) using methods known to those skilled in the art. Treatment of **K-3** then with HET-OM, wherein M is an alkali metal or silver for example, provides the heteroaryl ethers **K-4** ($A = O$) as well. The heteroaryl thioethers **K-4** ($A = S$) can similarly be prepared from the alkyl halides, mesylates or tosylates **K-3** by treatment with het-SM (M as defined above) or with
- 25 het-SH in the presence of a base such as DBU. The alcohols **K-2** can also be treated with het-NH-Pg, wherein Pg is a protecting group such as BOC, in the presence, for example, of tributylphosphine and 1,1'-(azodicarbonyl)dipiperidine (Mitsunobu conditions). The protecting group (Pg) can then be removed using methods known to those skilled in the art to provide the corresponding heteroaryl amines **K-4** ($A = \text{NH}$).
- 30 Alternatively, the alkyl halides, mesylates or tosylate **K-3** can be treated with het-NM-Pg or het-NHM, wherein M is lithium or sodium for example, and the protecting group (Pg) can be removed as before to afford the heteroaryl amines **K-4** ($A = \text{NH}$). The het starting materials used in these procedures (i.e., het-OH, het-SH, het-Lg, het-NH₂ and het-NH-Pg) are either commercially available or can be prepared

by methods described in WO 99/64416, WO 99/64417 and WO 00/21960 or by methods known to those skilled in the art.

As shown in Scheme L, acetophenones which are commercially available or readily accessed by those skilled in the art when treated with thallium (III) nitrate trihydrate and 70% perchloric acid in methanol or ethanol (*JACS*, **1971**, 93, 4919-4920) will yield the esters **L-2**. Alternatively, **L-1** may be converted to **L-2** under Willgerodt-Kindler conditions (*J. Heterocyclic Chem.* **1989**, 26, 1319-1323) by heating **L-1** with sulfur in morpholine followed by hydrolysis with hydrochloric acid. Treatment of **L-2** with sodium hydride in ethylformate will yield the formylated derivatives **L-3**. The isoxazolinone rings can be prepared by treating **L-3** with aqueous hydroxylamine in methanol. The solvent can be stripped off in vacuo and the residue treated with N-(hydroxymethyl)acetamide acetate in dichloromethane with a suitable base such as potassium carbonate. This process yields the products **L-4**. The requisite N-(hydroxymethyl)acetamide acetate is prepared as described by WO 00/10566.

The thioamides **L-5** (W = S) can be prepared by treating **L-4** with Lawesson's reagent in tetrahydrofuran, dioxane or toluene at temperatures ranging from 50-110 °C.

These compounds are useful for the treatment of microbial infections, including ophthalmologic infections, in humans and other warm blooded animals, under both parenteral and oral administration.

The pharmaceutical compositions of this invention may be prepared by combining the compounds of Formula I of this invention with a solid or liquid pharmaceutically acceptable carrier and, optionally, with pharmaceutically acceptable adjuvants and excipients employing standard and conventional techniques. Solid form compositions include powders, tablets, dispersible granules, capsules, cachets and suppositories. A solid carrier can be at least one substance which may also function as a diluent, flavoring agent, solubilizer, lubricant, suspending agent, binder, tablet disintegrating agent, and encapsulating agent. Inert solid carriers include magnesium carbonate, magnesium stearate, talc, sugar, lactose, pectin, dextrin, starch, gelatin, cellulosic materials, low melting wax, cocoa butter, and the like. Liquid form compositions include solutions, suspensions and emulsions. For example, there may be provided solutions of the compounds of this invention dissolved in water and water-propylene glycol and water-polyethylene glycol systems, optionally containing

suitable conventional coloring agents, flavoring agents, stabilizers and thickening agents.

Preferably, the pharmaceutical composition is provided employing conventional techniques in unit dosage form containing effective or appropriate amounts of the active component, that is, the compounds of formula I according to this invention.

The quantity of active component, that is the compound of formula I according to this invention, in the pharmaceutical composition and unit dosage form thereof may be varied or adjusted widely depending upon the particular application, the potency of the particular compound and the desired concentration. Generally, the quantity of active component will range between 0.5% to 90% by weight of the composition.

In therapeutic use for treating, or combating, bacterial infections in warm-blooded animals, the compounds or pharmaceutical compositions thereof will be administered orally, topically, transdermally, and/or parenterally at a dosage to obtain and maintain a concentration, that is, an amount, or blood-level of active component in the animal undergoing treatment which will be antibacterially effective. Generally, such antibacterially effective amount of dosage of active component will be in the range of about 0.1 to about 150, more preferably about 3.0 to about 100 mg/kg of body weight/day. A single 600 mg dose per day by IV or oral is preferred. It is to be understood that the dosages may vary depending upon the requirements of the patient, the severity of the bacterial infection being treated, and the particular compound being used. Also, it is to be understood that the initial dosage administered may be increased beyond the above upper level in order to rapidly achieve the desired blood-level or the initial dosage may be smaller than the optimum and the daily dosage may be progressively increased during the course of treatment depending on the particular situation. If desired, the daily dose may also be divided into multiple doses for administration, e.g., two to four times per day.

The compounds of formula I according to this invention are administered parenterally, i.e., by injection, for example, by intravenous injection or by other parenteral routes of administration. Pharmaceutical compositions for parenteral administration will generally contain a pharmaceutically acceptable amount of the compound according to formula I as a soluble salt (acid addition salt or base salt) dissolved in a pharmaceutically acceptable liquid carrier such as, for example, water-for-injection and a buffer to provide a suitably buffered isotonic solution, for example,

having a pH of about 3.5-6. Suitable buffering agents include, for example, trisodium orthophosphate, sodium bicarbonate, sodium citrate, N-methylglucamine, L(+)-lysine and L(+)-arginine to name but a few representative buffering agents. The compounds according to formula I generally will be dissolved in the carrier in an amount

5 sufficient to provide a pharmaceutically acceptable injectable concentration in the range of about 1 mg/ml to about 400 mg/ml of solution. The resulting liquid pharmaceutical composition will be administered so as to obtain the above-mentioned antibacterially effective amount of dosage. The compounds of formula I according to this invention are advantageously administered orally in solid and liquid dosage

10 forms.

EXAMPLES

Example 1 (-)-Methyl 6-[(5S)-5-[(acetylamino)methyl]-2-oxo-3-oxazolidinyl]-3,4-dihydro-2(1*H*)-isoquinolinecarboxylate

5 Step 1 Preparation of N-benzyl-6-nitro-1,2,3,4-tetrahydroisoquinoline

A solution of 2-[2-(hydroxymethyl)-5-nitrophenyl]ethanol (5.95 g, 30.17 mmol, *J. Org. Chem.*, **1998**, 63, 4116-4119) and triethylamine (10.51 mL, 75.42 mmol) in dry CH₂Cl₂ (121 mL) at 0°C under N₂ is treated with methanesulfonyl chloride (5.37 mL, 69.39 mmol) dropwise and stirred at 0°C for 30 mins. The mixture is then washed with 1M aqueous HCl (100 mL), saturated aqueous NaHCO₃ (100 mL) and brine (100 mL), dried over Na₂SO₄ and concentrated under reduced pressure to give the dimesylate intermediate [R_f = 0.77 by TLC (MeOH/CHCl₃, 10/90)] as a partially crystalline oil. To a solution of this oil in CH₂Cl₂ (151 mL) under N₂ is added benzylamine (16.48 mL, 150.8 mmol), and the resulting mixture is stirred at ambient temperature for 22 hrs and is then washed with water (100 mL) and brine (100 mL), dried over anhydrous Na₂SO₄ and concentrated under reduced pressure. The crude product is purified by silica gel chromatography (350g, 230 – 400 mesh), eluting with EtOAc/heptane (10/90), to give 7.76 g (96 %) of the title compound [R_f = 0.43 by TLC (EtOAc/hexane, 25/75)] as a light yellow solid, mp 76 - 78°C.

20 Step 2 Preparation of phenylmethyl 3,4-dihydro-6-
[[phenylmethoxy]carbonyl]amino]-2(1*H*)-isoquinolinecarboxylate

A solution of N-benzyl-6-nitro-1,2,3,4-tetrahydroisoquinoline (Step 1, 7.75 g, 28.99 mmol) in THF/MeOH (20/80, 290 mL) is added to two Parr bottles containing 10 % Pd/C (1.54 g each), and the mixtures are shaken under 45 psi H₂ for a total of 3.5 hrs. The catalyst is then removed by filtration through Celite and the combined filtrate is concentrated under reduced pressure to give the crude 6-amino-1,2,3,4-tetrahydroisoquinoline intermediate as a partially crystalline oil [R_f = 0.03 by TLC (MeOH/CHCl₃, 10/90)]. A mixture of this intermediate and NaHCO₃ (5.36 g, 63.78 mmol) in THF/H₂O (2/1, 116 mL) at 0°C is treated with benzyl chloroformate (9.11 mL, 63.78 mmol) dropwise, and the resulting mixture is stirred at 0°C for approximately 45 mins, additional THF/H₂O (2/1, 116 mL) being added after 15 mins. The layers are then separated, the organic phase is washed with saturated aqueous

NaHCO₃ (100 mL), the combined aqueous phase is reextracted with EtOAc (100 mL), and the combined organic phase is washed with brine (50 mL), dried over anhydrous Na₂SO₄, and concentrated under reduced pressure to give the crude product which is then chromatographed on silica gel (350 g, 230 – 400 mesh), eluting with a gradient of EtOAc/heptane (7.5/92.5 – 20/80). Pooling and concentration of those fractions with an R_f = 0.24 by TLC (EtOAc/hexane, 25/75) and recrystallization from EtOAc (75 mL)/hexane (175 mL) provides 7.10 g (59 %) of the title compound as a white solid, mp 115 - 116°C. An additional 2.0 g of impure product is isolated in the recrystallization.

10 Step 3 Preparation of (+)-phenylmethyl 6-[(5R)-5-(hydroxymethyl)-2-oxo-3-oxazolidinyl]-3,4-dihydro-2(1H)-isoquinolinecarboxylate

A solution of 3,4-dihydro-6-[[[phenylmethoxy]carbonyl]amino]-2(1H)-isoquinolinecarboxylate (Step 2, 7.05 g, 16.93 mmol) in dry THF (85 mL) at -78°C under N₂ is treated with n-butyllithium (11.1 mL, 1.6M in hexanes, 17.77 mmol) dropwise over 10 mins. The resulting mixture is stirred at -78°C for 45 mins and is then treated with (R)-(-)-glycidyl butyrate (2.52 mL, 17.77 mmol) dropwise. The resulting mixture is stirred at -78°C for 30 mins and is then warmed to ambient temperature and stirred for an additional 20 hrs. The reaction is then quenched with saturated aqueous NH₄Cl (25 mL), diluted with H₂O (25 mL) and extracted with EtOAc (100 mL). The organic phase is washed with H₂O (2 x 50 mL) and brine (25 mL), dried over anhydrous MgSO₄ and concentrated under reduced pressure to give the crude product which is then chromatographed on silica gel (350 g, 230 – 400 mesh), eluting with a gradient of MeOH/CH₂Cl₂ (1/99 – 3/97). Pooling and concentration of those fractions with an R_f = 0.29 by TLC (MeOH/CHCl₃, 5/95) provides 4.48 g (69 %) of the title compound as an amorphous, white solid. ¹H NMR (400 MHz, CDCl₃) δ 7.37 (m, 7H), 7.11 (m, 1H), 5.19 (s, 2H), 4.75 (m, 1H), 4.63 (s, 2H), 4.00 (m, 3H), 3.75 (m, 3H), 2.86 (m, 2H), 1.65 (bs, 1H); MS (ESI+) for C₂₁H₂₂N₂O₅ m/z 383 (M+H)⁺; [α]_D²⁵ = 16° (c 0.52, chloroform).

30 Step 4 Preparation of (-)-phenylmethyl 6-[(5S)-5-(aminomethyl)-2-oxo-3-oxazolidinyl]-3,4-dihydro-2(1H)-isoquinolinecarboxylate

A solution of phenylmethyl 6-[(5R)-5-(hydroxymethyl)-2-oxo-3-oxazolidinyl]-3,4-dihydro-2(1H)-isoquinolinecarboxylate (Step 3, 4.36 g, 11.40 mmol) and triethylamine (2.38 mL, 17.10 mmol) in dry CH₂Cl₂ (57 mL) at 0°C under N₂ is

treated with methanesulfonyl chloride (0.97 mL, 12.54 mmol) dropwise and stirred at 0°C for 1 hr. The mixture is then diluted with CH₂Cl₂ (60 mL), washed with H₂O (25 mL) and brine (25 mL), dried over Na₂SO₄ and concentrated under reduced pressure to give the mesylate intermediate [$R_f = 0.61$ by TLC (MeOH/CHCl₃, 5/95)] as an amorphous, white solid which is used without further purification. A mixture of this intermediate and concentrated aqueous NH₄OH (9.1 mL) in isopropanol (4.6 mL) and acetonitrile (9.1 mL) is placed in a thick-walled screw-cap tube and immersed in an oil bath maintained at 80°C and the contents are stirred at this temperature for 40 hrs, during which additional concentrated aqueous NH₄OH (4 mL) is added. The mixture is then cooled to ambient temperature, diluted with half-saturated aqueous NaCl (50 mL) and extracted with CH₂Cl₂ (2 x 100 mL).
